

Checklist of Japanese Earthworms updated from Easton (1981)

by R.J. Blakemore

C/-, Soil Ecology Group, Yokohama National University, Japan.

Summary

The current list is about 82 valid species in seven families from Japan. Previous revisions by Easton (1981) had listed 73 or 74 species and Blakemore (2003) provisionally catalogued 76 valid earthworm taxa, with approximately 80 further names (ca. 50% of the total) either in synonymy or retained as *species incertae sedis*. Some 60 or so “new” *Pheretima* names with strange genus and species definition had been added by Ishizuka in 1999-2001 that, mostly ignorant of ICBN (1999), had but a few considered valid taxa with the majority being synonyms, homonyms [such as the permanently invalid primary homonym *Pheretima montana* 1999 (non Kinberg, 1867 – the type species of the genus)] or *species incertae sedis* and, as yet, no native *Pheretima* s. stricto are known from Japan.

About 30 species are known introductions with four “new records” by the current author, and another ten are possibly more widespread (e.g. in Korea/China), thus the probable number of wholly endemic Japanese earthworms is around 40 species (ca. 50% of the total valid species). A subsequent report of *Amyntas rodericensis* (Grube, 1879) from Japan by a non-specialist is dubious and unconfirmed. However, a definitive work on the systematics of all of Japan’s earthworms is pending, relying partly on review of all of Japan’s and Korea’s classical species, and partly on more systematic on the ground eco-taxonomic surveys.

While much of Easton’s synopsis is supported, *Pontodrilus* is now placed in Megascolecidae sensu Blakemore (2000) rather than Acanthodrilidae sensu Gates

(1959); *Amyntas carnosus* (Goto & Hatai, 1899) is removed from synonymy of *Amyntas gracilis*; and an informal *Amyntas corticis* species-complex is established to accommodate the various morphs of this widely distributed species group. *Pheretima (Parapheretima) koellikeri* Michaelsen, 1928 - previously considered synonymous with the prior *Metaphire vesiculata* (Goto & Hatai, 1899) - is provisionally restored (it may be an introduced taxon). *Polypheretima* is also removed from Japanese indigeny as the original description of *Polypheretima iizukai* (Goto & Hatai, 1899) failed to report intestinal caeca and inspection of fresh material allows its placement in synonymy of *Amyntas fuscatus* (Goto & Hatai, 1898). Several new combinations by transfer to or from *Amyntas* and *Metaphire* were made. The *Metaphire hilgendorfi* / *Amyntas tokioensis* species-complex (*Amyntas hilgendorfi* species-complex sensu Easton, 1981) remains one of the most intractable and pressing problems for comprehension of the Japanese and Eastern Oriental fauna as it comprises a complex of parthenogenetically degraded morphs yet to be affiliated with their ancestral and biparental populations.
